

phase transformations in steels pdf

Dual-phase steels (DP steels) consist of ferrite and a dispersed hard martensitic second phase in the form of islands. Usually they are low-carbon low-alloy materials with 10-40 vol.% hard martensite or martensite-austenite particles embedded in a ductile ferrite matrix.

Martensite, named after the German metallurgist Adolf Martens (1850–1914), most commonly refers to a very hard form of steel crystalline structure, but it can also refer to any crystal structure that is formed by diffusionless transformation.

TWIP steels, which stands for twinning-induced plasticity steels, have received very high interest in recent years due to their excellent mechanical properties at room temperature combining high strength (ultimate tensile strength of up to 1 GPa) and ductility (elongation to fracture up to 100%) based on a high work-hardening capacity.

Crystal twinning occurs when two separate crystals share some of the same crystal lattice points in a symmetrical manner. The result is an intergrowth of two separate crystals in a variety of specific configurations.

ASTM's steel standards are instrumental in classifying, evaluating, and specifying the material, chemical, mechanical, and metallurgical properties of the different types of steels, which are primarily used in the production of mechanical components, industrial parts, and construction elements, as well as other accessories related to them.

Materials science and engineering is a discipline that extends from the microscopic structure and properties of materials to the design and evaluation of materials in engineering systems.
